

Homework 2 - Deep Neural Networks, Classifiers & Features

Due Date: 11.5.2020

Submission Guidelines

READ THIS CAREFULLY

- · Submission only in pairs.
- · No handwritten submissions.
- You can choose your working environment:
 - You can work in a Jupyter Notebook , locally with <u>Anaconda (https://www.anaconda.com/distribution/)</u> or online on <u>Google Colab (https://colab.research.google.com/)</u>
 - \circ Colab also supports running code on GPU, so if you don't have one, Colab is the way to go. To enable GPU on Colab, in the menu: Runtime \to Change Runtime Type \to GPU.
 - You can work in a Python IDE such as <u>PyCharm (https://www.jetbrains.com/pycharm/)</u> or <u>Visual Studio Code (https://code.visualstudio.com/)</u>.
 - Both also allow opening/editing Jupyter Notebooks.
- · You should submit two separated files:
 - A compressed .zip file, with the name: ee046746_hw2_id1_id2.zip which contains:
 - A folder named code with all the code files inside (.py or .ipynb ONLY!), and all the files required for the code to run (your own images/videos).
 - The code should run both on CPU and GPU without manual modifications, require no special preparation and run on every computer.
 - A report file (visualizations, discussing the results and answering the questions) in a .pdf format, with the name
 ee046746_hw2_id1_id2.pdf.
 - Be precise, we expect on point answers.
 - No other file-types (.docx , .html , ...) will be accepted.
- Submission on the course website (Moodle).

- numpy
- matplotlib
- pytorch (and torchvision)
- opencv (or scikit-image)
- scikit-learn
- Anything else you need (${\tt PIL}$, os , pandas , ${\tt csv}$, ${\tt json}$,...)

- In all tasks, you should document your process and results in a report file (which will be saved as .pdf).
- You can reference your code in the report file, but no need for actual code in this file, the code is submitted in a seprate folder as explained above.

In this part you are going to design a deep convolutional neural network to classify house number digits from the **The Street View House Numbers** (SVHN) Dataset.

SVHN is a real-world image dataset for developing machine learning and object recognition algorithms with minimal requirement on data preprocessing and formatting. It can be seen as similar in flavor to MNIST (e.g., the images are of small cropped digits), but incorporates an order of magnitude more labeled data (over 600,000 digit images) and comes from a significantly harder, unsolved, real world problem (recognizing digits and numbers in natural scene images). SVHN is obtained from house numbers in Google Street View images.

- 10 classes, 1 for each digit. Digit '0' has label 0, '1' has label 1,...
- 73257 digits for training, 26032 digits for testing, and 531131 additional, somewhat less difficult samples, to use as extra training data.

- 1. Load the SVHN dataset with PyTorch using torchvision.datasets.SVHN(root, split='train', transform=None, target_transform=None, download=True), you can read more here: https://pytorch.org/docs/stable/torchvision/datasets.html#svhn). Display 5 images from the train set.
- 2. Design a Convolutional Neural Network (CNN) to classify digits from the images.
 - Describe the chosen architecture, how many layers? What activations did you choose? What are the filter sizes? Did you use fully-connected layers (if you did, explain their sizes)?
 - What is the input dimension? What is the output dimension?
 - · Calculate the number of parameters (weights) in the network.
- 3. Train the classifier (preferably on a GPU use Colab for this part if you don't have a GPU).
 - Describe the the hyper-parameters of the model (batch size, epochs, learning rate....). How did you tune your model? Did you use a validation set to tune the model?
 - What is the final accuracy on the test set?

In this part you are going to analyze a (large) pre-trained model. Pre-trained models are quite popular these days, as big companies can train really large models on large datasets (something that personal users can't do as they lack the sufficient hardware). These pre-trained models can be used to fine-tune on other/small dataets or used as components in other tasks (like using a pre-trained classifier for object detection).

All pre-trained models expect input images normalized in the same way, i.e. mini-batches of 3-channel RGB images of shape $(3 \times H \times W)$, where H and W are expected to be at least 224. The images have to be loaded in to a range of [0, 1] and then normalized using mean = [0.485, 0.456, 0.406] and std = [0.229, 0.224, 0.225].

You can use the following transform to normalize:

```
normalize = transforms.Normalize(mean=[0.485, 0.456, 0.406], std=[0.229, 0.224, 0.225])
```

Read more: https://pytorch.org/docs/stable/torchvision/models.html (https://pytorch.org/docs/stable/torchvision/models.html)

- 1. Load a pre-trained VGG16 with PyTorch using torchvision.models.vgg16(pretrained=True, progress=True, **kwargs), you can read more here: https://pytorch.org/docs/stable/torchvision/models.html#classification). Don't forget to use the model in evaluation mode (model.eval()).
- 2. Load the images in the ./birds folder and display them.
- 3. Pre-process the images to fit VGG16's architecture. What steps did you take?
- 4. Feed the images (forward pass) to the model. What are the outputs?
- 5. Find an image of a bird/cat/dog on the internet, display it and feed it to network. What are the outputs?
- 6. Apply the following 3 transformations to create 3 new images from the image from step 5, and display them (opencv has functions for all):
 - One geometric transformation (rotation, scaling, translation, warping...).
 - One color transformation (thresholding, different color space, hue, saturation, brightness, contrast...).
 - · One filter (any filter you want).
- 7. Feed the transformed images to network, what is the output? is different than section 5?
- 8. For the first 3 filters in the *first layer* of VGG16, plot the filters, and then plot their response (their output) for the image from section 5 and the 3 images from section 6 (total of 4 input images). Consult ee046746_appndx_visualizing_cnn_filters.ipynb to refresh your memory. Explain what do you see.
- 9. For each image in the ./dogs and ./cats folders, extract and save their feature vectors (create a numpy array or a torch tensor that contains the features for all samples) from a fully-connected layer (such as FC7) of the VGG16 model (you need to write a function that does the feed forward manually until the desired layer, there is an example in ee046746_appndx_visualizing_cnn_filters.ipynb). Which layer did you pick? What is the size of the feature space?
- 10. Build a Support Vector Machine (SVM) classifier (sklearn.svm.LinearSVC) to classify cats and dogs based on the features you extracted. Use the 20 images as train set, and choose 4 images (2 dogs, 2 cats) from the internet as test sets. You can choose a different classifer than SVM from the scikit-learn library, no need to explain how it works (but report the name of the algorithm you used). What are the results?
